ARC-TUNNEL EVALUATION OF SOME
ABLATIVE HEAT SHIELD MATERIALS
FOR THE X-15-2

By Andrew J. Chapman
and Marvin B. Dow
Langley Research Center

SUMMARY

[Fourteen ablation materials have been investigated at test conditions simulating the heating predicted for the X-15-2 research aircraft. Twenty-seven wedge-shaped models with a leading-edge radius similar to the X-15-2 wing and horizontal stabilizer leading edges were tested in the 2-inch supersonic arc tunnel at the Langley Research Center. The ablation materials were exposed to the heating conditions which will occur on the X-15-2 leading edges and fuselage areas at an altitude of 105 000 feet (32 kilometers) and at Mach number 8. The results presented include back surface temperature response at several locations on the models and photographs of the models before and after testing.]

INTRODUCTION

One of the three existing X-15 research aircraft (X-15-2) has been modified to obtain a significant increase in velocity. The modification discussed in reference 1 includes increased propellant capacity which will permit acceleration to a maximum speed of approximately Mach 8 as compared with a maximum speed of approximately Mach 6 previously attained by the unmodified X-15. Some of the flight profiles proposed for the X-15-2 will produce heating conditions which will exceed the design capability of the present structure which is made of a nickel-chromium alloy. For example, calculations indicate that one flight profile with a maximum velocity of 8000 ft/sec (2400 m/s) at an altitude of 100 000 feet (30 kilometers) will produce temperatures as high as 2400° F (1600° K) on wing and tail leading edges. A decision has been made to use an ablative coating on the entire aircraft to provide the required heat shielding rather than to redesign the aircraft structure.

Several types of ablation materials have been investigated for use on the X-15-2 aircraft. Flight tests with the X-15 have been conducted by the NASA Flight Research Center at speeds of about Mach 5.5. In these flight tests, small areas of the fuselage were

covered with ablation material for performance evaluation. Tests were also conducted in ground facilities in which various ablation materials were exposed to simulated X-15-2 flight conditions. The various ablation materials were evaluated for compliance with the criteria for the ablative heat shield system established by the NASA Flight Research Center (ref. 1). Evaluation of one ablation material is included in reference 1.

As a result of the flight and ground facility tests mentioned previously, those ablative materials which most nearly satisfied the established criteria were chosen for further evaluation. These materials were then tested in the 2-inch supersonic arc tunnel at the Langley Research Center and are reported herein. Some of these results were reported previously in reference 2. The test conditions simulated heating conditions encountered on wing or horizontal stabilizer leading edges and on certain fuselage areas at Mach number 8 and an altitude of 105 000 feet (32 kilometers). The purpose of these tests was to investigate the thermal performance of the various materials. It was not intended that the tests should provide design data.

The units used for physical quantities in this paper are given both in U.S. Customary Units and in the International System of Units (SI) (ref. 3). The appendix presents factors relating these two systems of units.

TEST MODELS

Ablative Coatings

The 14 different materials tested in this investigation were furnished by four aerospace companies and by the NASA Langley Research Center. Many of the materials, however, differed only in minor features such as density, additives, and methods of application. The materials are listed in table 1. The information in this table includes the composition, the specific gravity, the type of model on which the material was tested (see section on "Configurations"), and the method used to apply the material to the model. A code designation is given to each material and this identification is used throughout the paper. The designation consists of a letter for each source and a number for different materials of a particular source.

Configurations

Two model configurations were used for testing the various ablation materials: a leading-edge model shown in figure 1 and a flat afterbody model shown in figure 2. The pertinent dimensions of each model are given in the figures. The models were the largest size which could be tested in the arc-tunnel facility at the present test conditions.

Leading-edge models.- Although both model configurations had a similar leading-edge shape, the first configuration will be referred to as the leading-edge model because

the ablative material was applied over the entire surface of the model with the primary purpose of testing the material at the stagnation region. This model consisted of a reinforced plastic frame covered by a 0.030-inch (0.076-cm) thick skin of a nickel-chromium alloy. The 0.50-inch (1.27-cm) leading-edge radius corresponds to the X-15 horizontal stabilizer. Thermocouples were attached to the back surface of the skin at the locations shown in figure 1. These positions are identified by numbers which are used subsequently in connection with temperature and thickness measurements. The models were constructed in two sections so that they could be easily separated to facilitate postexposure examination after the ablative coating had been cut along the center line.

The exterior shape of the ablative coating is shown as a dashed line in figure 1. The coating thickness was varied, according to the density of the material, to give a specified mass per unit area at the stagnation line. The only exterior dimensions changed by varying the coating thickness were the overall length L of the model and the total thickness at the base B . The nominal values of stagnation line mass per unit area were 1.0 lbm/ft^2 (4.9 kg/m^2) and 1.5 lbm/ft^2 (7.3 kg/m^2) for this program. In addition to the test material on the contoured surface, an ablative coating was applied to each side of the model to protect the plastic structure. (See fig. 1.)

Eleven ablation materials were tested on 21 leading-edge models which are identified in table 2(a). The pretest thicknesses of the ablation materials at the different thermocouple locations are shown in table 2(a) for all models for which this information was available. The ablation material thicknesses were constant in the spanwise direction. Models L-16 and L-17 were the only leading-edge models on which more than one type of ablation material was applied.

Flat afterbody models.— The afterbody model configuration is shown in figure 2. This model was of hollow stainless-steel construction and was cooled by circulating water. Test panels of ablative materials were mounted in recessed areas on each side of the model. The purpose of this configuration was to test thin coatings of material at the low heating rate and pressure conditions which will occur over much of the aircraft surface. The water-cooled model permitted exposure periods which were limited only by the performance of the test material.

The test panels consisted of a thin sheet of ablative material bonded to a 0.03-inch (0.08-cm) thick plate of a nickel-chromium alloy which had thermocouples attached to the back surface. Details of the instrumentation are shown in figure 2. The ablation materials were of a thickness which gave a nominal mass per unit area of 0.25 lbm/ft^2 (1.22 kg/m^2). The cutout area on the model was 0.25 inch (0.64 cm) deep so that an additional layer of spacing material was needed between the panel and the model to position the panel surface flush with the model surface. This spacing material, which was a

low-density filled silicone resin, also served as insulation to isolate the nickel-chromium alloy substrate plate from the water-cooled model.

Four ablative materials were tested on six afterbody models. The models and materials are listed in table 2(b). The ablative materials are identified by the code designation used in table 1. Each afterbody model had an A-2 panel on one side and a panel of one of the three commercial materials on the opposite side. The thickness of the ablative material before testing is given in table 2(b).

TEST CONDITIONS AND PROCEDURE

Test Facility

The 2-inch supersonic arc tunnel at the Langley Research Center was used for testing. This facility is described for a subsonic configuration in references 4 and 5. The pertinent mechanical and electrical features remained unchanged for this investigation except that for the present tests the tunnel has been equipped with a supersonic nozzle and provisions for exhausting into a vacuum chamber. A schematic diagram of the tunnel is shown in figure 3. A conical nozzle with a throat diameter of 1.5 inches (3.8 cm) and an exit diameter of 4 inches (10.2 cm) was used.

Test Conditions

The arc-tunnel test conditions are as follows:

Total enthalpy	1450 Btu/lbm (3.36 MJ/kg)
Free-stream Mach number	3.2
Model stagnation pressure	0.73 atm (74 kN/m ²)
Heat-transfer rate at model stagnation point	127 Btu/ft ² -sec (1.44 MW/m ²)
Shear force at sonic line (ratio of surface distance to leading-edge radius equal 0.72)	4 lbf/ft ² (190 N/m ²)

The curves of figure 4 show the total enthalpy, the wing leading-edge heating rate, and the total pressure for a proposed Mach 8 flight of the X-15-2. Corresponding conditions obtained in the arc tunnel are superimposed on the flight conditions. Although the Mach number in the arc tunnel was only 3.2, a good simulation of maximum enthalpy and maximum pressure was obtained. Inasmuch as tunnel operation was limited to steady-state conditions, it was not possible to simulate an entire flight history. Test conditions, therefore, were selected which simulated the more severe heating period of the flight. Arc-tunnel limitations also prevented testing with the model leading edge at a sweep angle similar to the X-15 leading edges. Therefore, all models were tested with the leading edge normal to the test stream.

Enthalpy.- Total enthalpy of the tunnel flow was determined by the sonic flow method described in reference 6. The enthalpy is determined by this method from the mass flow rate, total pressure, and nozzle minimum area. There was good agreement between enthalpy values obtained by the sonic flow method and values obtained by an energy balance.

Pressure distribution.- Several pressure measurements were made on a calibration model having the same external shape as the test models. These pressure measurements are plotted in figure 5 and show good agreement with the Newtonian pressure-distribution curve.

Heating rate.- The heating rates were measured with a 0.017-inch (0.043-cm) thick 301 stainless-steel calorimeter model having the same exterior shape and dimensions as the test models. Heating rate distributions on the calorimeter model from several different calibration tests are shown in figure 6.

Test Procedure

For each test of an ablative material the tunnel operating conditions determined from previous calibration tests were established. The model was then inserted into the test stream. During tests of the leading-edge models the outputs from the four thermocouples located on the stagnation line (see fig. 1) were monitored on a visual display. When the temperature at any one of these thermocouples reached 600°F (590°K) the model was withdrawn from the test section. During tests of the afterbody panels the outputs from thermocouples 1-a and 1-b at the center of the panel (see fig. 2) were monitored and the tests were terminated when one of these thermocouples indicated a temperature of 600°F (590°K). After the leading-edge and afterbody models were withdrawn from the test stream, temperatures were recorded until maximum values occurred. Pressure in the test section and model storage chamber was then increased slowly to atmospheric pressure to avoid damage to the decomposed ablative coating.

All temperature and pressure data were recorded by the Langley central digital data recording facility.

RESULTS AND DISCUSSION

An index of tables and figures showing test results is given in table 3.

Leading-Edge Models

Photographs of the leading-edge models are shown in figures 7 to 16. Each figure shows models with one particular coating and includes a photograph of a typical model before testing, post-test exterior views showing an eight-view sequence of model surfaces,

and center-line section views. Materials A-1, A-2, A-3, B-2, C-2, D-3, and E-1 were tested with a nominal mass per unit area of 1.0 lbm/ft^2 (4.9 kg/m^2) on the stagnation line of the model. Materials B-1, C-1, and D-1 were tested with a nominal mass per unit area of 1.5 lbm/ft^2 (7.3 kg/m^2) on the stagnation line.

The photographs show that most of the leading-edge materials were severely affected by the test environment, particularly at the region near the stagnation line. Only material D-1, a relatively high-density heavily reinforced composite, maintained a smooth unbroken surface in all tests. However, both models L-16 and L-17 showed post-test separation at the junction between the D-1 material and the D-2 elastomeric material on the model afterbody.

Model L-1 of material A-1 withstood the test environment without experiencing severe defects or material removal. Examination of this material after testing indicated that the interface between the char layer and the undegraded material on the nose radius, although separated, was extensively interlaced with glass fibers. Apparently the material had good adhesion to the glass fibers which in turn made the material resistant to cracking and removal by shear. However, model L-2 of material A-1 experienced a failure at one end of the stagnation area. (See fig. 7(d).) Severe local heating caused extensive melting in the failure area and prevented a determination of whether lack of fiber reinforcement caused the failure. Although model L-1 performed well, the failure of model L-2 indicated inconsistent performance for material A-1 in the test environment.

The sprayed leading-edge materials A-2 and E-1, which were similar in composition to material A-1, appeared to be weak in resistance to shear forces. Severe loss of both of these materials occurred at the region of high shear at the spanwise edge of the models. In the case of material E-1, the hard glassy char layer noted for the other elastomeric materials separated during handling immediately after the tests.

Material A-3, a low-density phenolic-nylon composite, was severely oxidized by the test environment. This result indicates an undesirable feature of this type of material for X-15 thermal protection.

Materials B-1 and B-2 both developed severe cracks at the model stagnation area. The substantial increase in the density of material B-1 as compared with that of material B-2 did not appear to influence the severity of cracking.

Material C-2 developed extensive fissures at the model stagnation area. The models coated with material C-1 experienced severe loss of the ablator on the stagnation line at the model ends.

Material D-3, a silicone elastomeric in honeycomb, was rapidly removed from the entire model stagnation area during the test.

A marked difference appeared in the residual material or char layer at various locations on the models coated with silicone elastomeric materials. The char layer produced at the high heating rate and pressure conditions at the stagnation area had a hard glassy appearance. When a layer of undegraded material remained on the stagnation area there was a well-defined interface between the char layer and the undegraded material. On most models there was evidence of separation at this interface. The residual material on the flat afterbodies was more friable with no glassy appearance. The defects in the afterbody residual material consisted of blisters and cracks which were much less severe than the stagnation area defects. The interface between residual material and undegraded material on the afterbody appeared to be a zone of decomposition and was not as well defined as on the nose radius. Also there was little separation along this interface.

Temperature histories for the leading-edge model thermocouples (see fig. 1) are given in tables 4 to 24. The time at which heating was terminated is indicated on the table for each test. Temperature histories on the stagnation line of leading-edge models are compared in figure 17 for materials A-1, B-1, C-1, and D-1, which represent the best leading-edge materials from each supplier. Material A-1 had a nominal mass per unit area of 1.0 lbm/ft^2 (4.9 kg/m^2) on the stagnation line whereas the other materials had a nominal mass per unit area of 1.5 lbm/ft^2 (7.3 kg/m^2). Material A-1, although of lower unit mass, limited the substrate temperature on model L-1 for a period comparable to that of material B-1 and for a longer period than the other materials. The high temperature rise at position 6 on model L-2 was a result of the failure at the edge of this model. Material C-1 was comparatively effective in limiting temperature rise at position 1; however, the severe loss of material at the model edge (figs. 12(b) and 12(d)) resulted in very high temperature rises at position 6. The temperature rise on the stagnation line of material D-1 was quite high. It should be noted, however, that the temperature histories along the stagnation line of coating D-1 were nearly identical and thus indicated uniform behavior of the material in this region. The low thermal performance of coating D-1 was to be expected since this relatively high-density material had higher thermal conductivity than the less dense materials.

Although the ablation materials were tested at heating conditions in the range predicted for Mach 8 flights of the X-15-2, the tests were in some respects less severe than flight conditions. For example, the materials were not restrained from expanding in a spanwise direction, the maximum calculated shear force on the models was less than that calculated for flight (see ref. 1), the ablation materials did not have joints parallel to the stream flow, and the model substructure did not deflect and thus impose loads on the ablation materials.

Flat Afterbody Models

Afterbody models of materials A-2, B-3, and C-3 before and after testing are shown in figures 18 to 20. Figure 21 shows the afterbody model of material D-4 before testing and the panels removed from the model after testing.

The post-test appearance of the ablation materials on the panels was similar to the post-test appearance of similar materials on the flat afterbody of the leading-edge models. The sprayed materials A-2, C-3, and D-4 had surface defects consisting of blisters and cracks. Some of these defects may have resulted from entrapment of volatile compounds (see ref. 7) during the spraying operation. These materials showed a gradient of decomposition through the thickness rather than a definite pyrolysis layer. The test of the D-4 panel on model P-5 was terminated before a temperature of 600° (580° K) was reached because of an arc-tunnel malfunction. The D-4 panel on model P-6 was severely damaged during testing as a result of the panel being blown off the model shortly after insertion into the arc-tunnel stream.

Material B-3, a blown foam, showed no obvious surface defects such as the blistering or cracking noted on the other materials. This material also showed a gradient of decomposition through the thickness.

Complete temperature histories for the afterbody models are given in tables 25 to 30. Each table contains data for a commercial panel and an A-2 panel since each model mounted a commercial and an A-2 panel on opposite sides. Thermocouple positions on the panels are identified by the numbers shown in figure 2. Temperature histories from thermocouples 1-a and 1-b for each panel are shown in figure 22. These temperature histories are a direct comparison of thermal shielding performance since each panel had the same nominal mass per unit area. Although the temperature histories for materials A-2, B-3, and C-3 show some differences between panels of the same material, there is little difference in the shielding performance of the three materials. As noted previously, the tests of the D-4 panels were terminated early. The curves of figure 22 show a faster initial temperature response for the D-4 panels than for panels with the other three materials. Since the density of material D-4 was considerably higher than the density of materials A-2, B-3, and C-3, it follows that for a given mass per unit area the higher density material would give reduced shielding performance.

CONCLUDING REMARKS

Fourteen ablation materials were tested on 27 models at conditions simulating the heating on the X-15-2 leading edges and fuselage areas at Mach 8 at an altitude of 105 000 feet (32 kilometers). The models were a wedge shape with a leading-edge radius and tangent surface angle similar to the X-15 wing and horizontal stabilizer. The

materials were investigated in the 2-inch supersonic arc tunnel at the Langley Research Center at a total enthalpy of 1450 Btu/lbm (3.36 MJ/kg), a heat-transfer rate of 127 Btu/ft²-sec (1.44 MW/m²), and a model stagnation pressure of 0.73 atm (74 kN/m²). Heat-transfer rate and pressure on the afterbody were approximately 10 percent of the stagnation values.

The conditions at the model stagnation region were a severe test for most of the ablation materials. The deficiencies, which occurred to varying degree on different materials, included rapid and irregular loss of material and the formation of deep cracks and fissures. The elastomeric materials were particularly prone to such deficiencies. One material, a relatively high-density phenolic bonded silica fiber composition, retained an unbroken surface at the stagnation region. This material, however, was inefficient as a thermal shield.

Several elastomeric materials were sprayed directly onto the models. The sprayed elastomers tested at the stagnation conditions showed markedly poor performance. The sprayed materials tested at the low heating rate and pressure conditions on the model afterbody developed defects such as shallow blisters and cracks. However, these defects did not appear to adversely affect thermal shielding performance. A particular precast elastomer tested at these conditions ablated uniformly and did not blister or crack.

APPENDIX

CONVERSION OF U.S. CUSTOMARY UNITS TO SI UNITS

The International System of Units (SI) was adopted in 1960 by the Eleventh General Conference on Weights and Measures held in Paris, France. A complete set of conversion factors and a description of the system is given in reference 3. Conversion factors for units used herein are given in the following table:

Physical quantity	U.S. Customary Unit	Conversion factor (*)	SI Unit
Enthalpy	Btu/lbm	2.32×10^3	J/kg
Force	lbf/ft ²	47.88	N/m ²
Heat-transfer rate	Btu/ft ² -sec	1.135×10^4	W/m ²
Heat load	Btu/ft ²	1.135×10^4	J/m ²
Length	{ ft	0.3048	m
	{ in.	0.0254	m
Mass per unit area	lbm/ft ²	4.88	kg/m ²
Pressure	atm	1.013×10^5	N/m ²
Temperature	°F	$5/9 (°F + 460)$	°K
Velocity	ft/sec	0.3048	m/s

*Multiply value given in U.S. Customary Unit by conversion factor to obtain equivalent value in SI Unit.

Prefixes to indicate multiples of units are as follows:

Prefix	Multiple
mega (M)	10^6
kilo (k)	10^3
centi (c)	10^{-2}

"The aeronautical and space activities of the United States shall be conducted so as to contribute . . . to the expansion of human knowledge of phenomena in the atmosphere and space. The Administration shall provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

—NATIONAL AERONAUTICS AND SPACE ACT OF 1958

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Technical information generated in connection with a NASA contract or grant and released under NASA auspices.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

TECHNICAL REPRINTS: Information derived from NASA activities and initially published in the form of journal articles.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities but not necessarily reporting the results of individual NASA-programmed scientific efforts. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

Details on the availability of these publications may be obtained from:
